MAC addresses and ARP

- 32-bit IP address:
 - network-layer address for interface
 - used for layer 3 (network layer) forwarding
- MAC (or LAN or physical or Ethernet) address:
 - function: used 'locally" to get frame from one interface to another physically-connected interface (same network, in IPaddressing sense)
 - 48 bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable

LAN addresses and ARP

each adapter on LAN has unique LAN address

LAN addresses (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
 - MAC address: like Social Security Number
 - IP address: like postal address
- ♦ MAC flat address → portability
 - can move LAN card from one LAN to another
- IP hierarchical address not portable
 - address depends on IP subnet to which node is attached

ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

- IP/MAC address mappings for some LAN nodes:
 - < IP address; MAC address; TTL>
- TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

ARP protocol: same LAN

- A wants to send datagram to B
 - B' s MAC address not in A' s ARP table.
- A broadcasts ARP query packet, containing B's IP address
 - dest MAC address = FF-FF-FF-FF-FF
 - all nodes on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
 - frame sent to A' s MAC address (unicast)

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
 - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
 - nodes create their ARP tables without intervention from net administrator

walkthrough: send datagram from A to B via R

- focus on addressing at IP (datagram) and MAC layer (frame)
- assume A knows B's IP address
- assume A knows IP address of first hop router, R (how?)
- assume A knows R's MAC address (how?)

- ✤ A creates IP datagram with IP source A, destination B
- A creates link-layer frame with R's MAC address as dest, frame contains A-to-B IP datagram

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

- * R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

- * R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

- * R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols
- 5.4 LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANS

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

Ethernet

"dominant" wired LAN technology:

- cheap \$20 for NIC
- first widely used LAN technology
- simpler, cheaper than token LANs and ATM
- kept up with speed race: 10 Mbps 10 Gbps

An example avionics communication network: AFDX network (Avionics Full Duplex Ethernet

(Figure from Airbus, more details can be found at: <u>http://www.artist-</u> <u>embedded.org/docs/Events/2007/IM</u> <u>A/Slides/ARTIST2_IMA_Itier.pdf</u>)

Ethernet: physical topology

- **bus:** popular through mid 90s
 - all nodes in same collision domain (can collide with each other)
- star: prevails today
 - active switch in center
 - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

Ethernet frame structure

sending adapter encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame

preamble:

- * 7 bytes with pattern 10101010 followed by one byte with pattern 10101011
- used to synchronize receiver, sender clock rates

Ethernet frame structure (more)

* addresses: 6 byte source, destination MAC addresses

- if adapter receives frame with matching destination address, or with broadcast address (e.g. ARP packet), it passes data in frame to network layer protocol
- otherwise, adapter discards frame
- type: indicates higher layer protocol (mostly IP but others possible, e.g., Novell IPX, AppleTalk)
- * CRC: cyclic redundancy check at receiver
 - error detected: frame is dropped

Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- unreliable: receiving NIC doesnt send acks or nacks to sending NIC
 - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD wth binary backoff

802.3 Ethernet standards: link & physical layers

- *many* different Ethernet standards
 - common MAC protocol and frame format
 - different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10G bps
 - different physical layer media: fiber, cable

Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols
- 5.4 LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANS

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

Ethernet switch

Iink-layer device: takes an active role

- store, forward Ethernet frames
- examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- transparent
 - hosts are unaware of presence of switches
- plug-and-play, self-learning
 - switches do not need to be configured

Switch: *multiple* simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, but no collisions; full duplex
 - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

Switch forwarding table

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

- <u>A</u>: each switch has a switch table, each entry:
 - (MAC address of host, interface to reach host, time stamp)
 - Iooks like a routing table!

<u>Q</u>: how are entries created, maintained in switch table?

something like a routing protocol?

switch with six interfaces (1,2,3,4,5,6)

Switch: self-learning

- switch *learns* which hosts can be reached through which interfaces
 - when frame received, switch "learns" location of sender: incoming LAN segment
 - records sender/location pair in switch table

MAC addr	interface	TTL
A	1	60

Switch table (initially empty)

Switch: frame filtering/forwarding

when frame received at switch:

- I. record incoming link, MAC address of sending host
- 2. index switch table using MAC destination address
- 3. if entry found for destination
 then {
 - if destination on segment from which frame arrived then drop frame
 - else forward frame on interface indicated by entry
 - else flood /* forward on all interfaces except arriving interface */

Self-learning, forwarding: example

/ Source: A / Dest: A'

- frame destination, A',
 locaton unknown: flood
- destination A location known: selectively send on just one link

MAC addr	interface	TTL
A	1	60
A'	4	60

switch table (initially empty)

Interconnecting switches

switches can be connected together

<u>Q</u>: sending from A to G - how does S_1 know to forward frame destined to F via S_4 and S_3 ?

A: self learning! (works exactly the same as in single-switch case!)

Self-learning multi-switch example

Suppose C sends frame to I, I responds to C

* Q: show switch tables and packet forwarding in S_1 , S_2 , S_3 , S_4

Switches vs. routers

both are store-and-forward:

routers: network-layer devices (examine networklayer headers)

switches: link-layer devices (examine link-layer headers)

both have forwarding tables:

routers: compute tables using routing algorithms, IP addresses

 switches: learn forwarding table using flooding, learning, MAC addresses
